

ALZHEIMER DISEASE

Informative genetic testing is currently available to only a small number of families with a history of early-onset (younger than 60-65 years of age) Alzheimer disease (AD). For these families, the benefits of genetic testing are limited and are mainly related to the individual's perception of the psychological advantages of knowing whether or not they are predisposed to develop AD. There remains no cure or effective preventive therapy for AD.

Genetic testing is not feasible for most individuals with AD at this time. Apolipoprotein E gene variations alone cannot be used to predict future disease occurrence. Rare families with a history of early-onset AD might be eligible for genetic testing, while families with multiple relatives affected with late-onset AD (60-65 years of age and older) might be eligible to participate in AD research studies.

WHAT IS ALZHEIMER DISEASE? ¹

Alzheimer disease (AD) is an adult-onset progressive dementia. It is relatively common and the overall lifetime risk of developing dementia is 10-12%. Seventy-five percent of AD cases are sporadic, of unknown cause and usually have late onset of symptoms. Twenty-five percent of AD cases are familial (i.e. ≥ 2 persons in family have AD) and are composed of two types:

- Early-onset familial AD with a mean age of onset < 60-65 years (<2%)
- Late-onset familial AD with a mean age of onset of >60-65 years (15-25%)

Three genes have been associated with early-onset familial AD – amyloid precursor protein (*APP*), presenilin 1 (*PSEN1*), and presenilin 2 (*PSEN2*). Each of the identified genes is involved in production of the amyloid β (A β) peptide, a major component of amyloid plaques. Early-onset familial AD follows an autosomal dominant inheritance pattern.¹

While information about the genetic factors involved in late-onset familial AD is limited, this type of AD has been associated with apolipoprotein E (APOE) gene variations. These are considered a risk modifier, especially APOE $\epsilon 4$. Some data suggest that a young asymptomatic person with two copies of the APOE $\epsilon 4$ allele may have an increased lifetime risk of developing AD and a lower age of onset of AD compared to persons who have only one or no copies of the APOE $\epsilon 4$ allele. Approximately 20-25% of the general population carry one or more copies of the APOE $\epsilon 4$ alleles.² Approximately 42% of persons with AD do NOT have an APOE $\epsilon 4$ allele.¹ APOE $\epsilon 4$ is neither necessary nor sufficient for the disease.³

Inheritance of AD is a complex interaction between genetic and environmental factors. With one affected first-degree relative, the risk of AD is approximately 20-25%.¹

RED FLAGS TO CONSIDER GENETIC TESTING OR GENETIC CONSULTATION

Genetic testing for AD is only available for a small number of families with early-onset familial AD, with testing likely to be initiated in a living affected relative. If a gene mutation is found, other family members are eligible for testing for the identified family mutation. Clinical testing is currently not available for late-onset familial AD or sporadic cases. When there are multiple related affected individuals, research testing may be available. APOE $\epsilon 4$ testing is not recommended for risk assessment because of low sensitivity and specificity.

Consider a genetics consult for individuals with:

- AD with age of onset <60-65 years
- Late-onset AD and multiple affected close relatives
- Close relatives of the above two types of patients
- A family member who has an identified mutation in the *APP*, *PSEN1* or *PSEN2* genes

See www.geneticseducation.ca for how to connect to your local genetics centre.

WHAT DOES THE GENETIC TEST RESULT MEAN?¹

Inheriting a mutation in *APP*, *PSEN1* or *PSEN2* gene causes early-onset familial AD.

HOW WILL GENETIC TESTING HELP YOU AND YOUR PATIENT?

In the case of genetic testing for early-onset familial AD, a positive test result for a known family gene mutation can result in:

- Relief from uncertainty
- An increased feeling of control
- Opportunity to plan life decisions

A negative test result for a known family gene mutation for early-onset familial AD can result in:

- Relief from fear of developing early-onset AD
- Knowledge that children are not at risk for early-onset AD

ARE THERE HARMS OR LIMITATIONS OF GENETIC TESTING?

Currently no cure or effective preventive therapy is available if a gene mutation is found. A positive test result for a known early-onset familial AD family gene mutation can result in:

- Adverse psychological reaction, family issues/distress
- Confidentiality issues

Insurance discrimination

- Historically, genetic testing in an asymptomatic individual may have affected their ability to obtain life, disability, critical illness, long-term care and/or extended health insurance. However, in 2017 Canada passed the Genetic Information Non-Discrimination Act (GNA) that protects individuals from the use of a genetic test result to prevent them from obtaining insurance.

A negative test result for a known familial early-onset familial AD gene mutation can result in survivor guilt.

When an individual with no known familial gene mutation has genetic testing, a negative result is not a definitive answer.
